Clinical efficacy of *Coleus forskohlii (Willd.) Briq.* (*Makandi*) in hypertension of geriatric population

Madhavi Jagtap, H. M. Chandola, and B. Ravishankar

**Abstract**

Hypertension is the most common psychosomatic disorder affecting 972 million people worldwide. The present clinical study deals with the effect of *Makandi* (*Coleus forskohlii (Willd.) Briq.*) *Ghana vati* and tablets of its powder in hypertension found in the geriatric age group (50-80 years). A total of 49 hypertensive patients fulfilling the diagnostic criteria were registered in two groups-Group I (*Ghana vati*) and Group II (*Churna* tablet). Out of 27 enrolled patients of group I, 21 patients completed the treatment. In Group II, out of 22 registered patients, a total of 20 patients completed the treatment. The effect of the therapy was assessed on the basis of changes in the systolic and diastolic blood pressures, in both sitting and supine positions; with *Manasa Bhava Pariksha, Manasa Vibhrama Pariksha*, symptomatology, geriatric signs and symptoms, and a brief psychiatric rating scale. Analysis of the results showed that the treatment in both the groups had been found to be good. It can be stated that *Makandi*, either in *Ghana vati* form or in *churna* tablet form, is an effective remedy for the treatment of hypertension. On analyzing the overall effect, 76.19% patients in Group I and 75.00% patients in Group II were mildly improved. Comparatively the overall treatment with group I was found to be better.

**Keywords:** *Makandi, Coleus forskohlii, forskolin, Ghana vati, geriatric hypertension*

**Introduction**

Hypertension is an important public-health challenge worldwide due to its associated morbidity, mortality, and economical burden on society. Worldwide, it has been seen in about 972 million people in 2000, and the prevalence has been estimated to increase by about 60% to a total of 1.56
billion by the year 2025.[1] It has been reported that hypertension prevalence in India quadrupled in the urban as well as rural populations over a 50-year period, from the early 1950s to the late 1990s.[2,3] Hypertension as such is not described in Ayurvedic literature, however, the spectrum of disease hypertension is interpreted in terms of Raktavata, Raktagatavata, and in recent years as Vyana bala vaishyama/Vyana bala vriddhi in Ayurvedic parlance.

The disease is associated with increased obesity and aging population. India now has the second largest aged population in the world.[4] The incidence rate of hypertension increases with age in both men and women due to age-related changes like thickening of vessel wall, arteriosclerosis, and so on, leading to a decrease in elasticity and lumen of the vessels, and hence, increase in blood pressure. Moreover feeling of insecurity, stress, and anxiety, causes a disturbance in mental health and precipitates the disease, which is frequently seen in old age. Also it is stated that Jara Avastha (old age) is the Parihani Kala having Vata dosha in dominancy, which is the main dosha involved in the pathogenesis of hypertension. It is more common in men than in women up to the age 50 years, after which blood pressure rises in women and becomes equal to that seen in males. In later life pressures are higher in women.

The treatment of hypertension in modern science is palliative in nature. Although pharmacological treatments are effective for controlling blood pressure, they have adverse side effects. Lack of information regarding the etiology of most cases of hypertension has enhanced the search for effective anti-hypertensive agents. This approach has led to a further hunt into indigenous drugs, especially after the invention of very promising results of reserpine. For preservation of the health of vital organs, the use of medicinal herbs is the need of the hour. There are a number of herbs that are used as home remedies for common ailments. Such herbs are easily available, eco-friendly, cost-effective, and toxicity-free, due to their holistic approach.

Coleus forskohlii (Willd.) Briq., [synonym C. barbatus (Andr.) Benth.], belonging to the family Labiatae, Genus-Coleus, is an ancient root drug mentioned in Ayurvedic Materia Medica,[5,6] under the Sanskrit name ‘Makandi’. It is stated to have Agnidipana, Pachana, Pandu, Pliha, Shothhara, and other such properties. In the recent monographs of Indian Council of Medical Research,[7] it is described by the name Gandir, with a Gujarati name of ‘Garamar’. It is commonly known as Garmar in the Saurashtra region of Gujarat, and is extensively used as pickle in almost every home during its season, around the months of March to May of each year. The species is being cultivated in Gujarat, Maharashtra, and Karnataka. The traditional uses of the plant are also reported.[8] The root tubers are used traditionally as blood purifiers, hypotensives, diuretics, and so on.

In 1974, researchers first isolated[9] the diterpene, Forskolin, having blood pressure lowering and antispasmodic effects, from the roots, making it the only plant source thus far known having this substance. The therapeutic effects of this alkaloid ‘forskolin’ are well-documented[10] as being a hypotensive, antispasmodic, positive inotrophic, vasodilator, smooth muscle relaxant, anti-inflammatory, with anti-platelet aggregation, a bronchodilator, anti-glaucoma agent, anti-metastatic, and so on, due to its unique ability to activate the enzyme, Adenylate cyclase, in the absence of a functional guanine nucleotide regulatory protein.
Very few clinical and experimental trials have been done on the *Churna* of the root (as a whole). No study has been reported on the effect of *Ghanavati* form of the drug using root tuber. Though many pharmacological and few clinical studies have been carried out on active principle or isolated fractions of the drug. This type of treatment is always discouraged by *Ayurveda*, as it believes in total and positive health. When a fraction is isolated it acquires a pin-pointed action and also develops the risk of creating adverse effects. The whole drug contains various fractions in balance, with the least chance of developing adverse effect. The administration of the total drug is always preferred by *Ayurveda*, so as to interfere in the least with the natural composition and action. Considering all these points, the present clinical trial was undertaken with the aim of finding efficacy of this whole root tuber, in cases of hypertension.

**Aims and objectives**

The aims of the study was to evaluate the efficacy of *Coleus forskohlii* (Willd.) Briq. (*Makandi*) root (tuber) *Ghana vati* and *Churna* tablet in hypertension observed in geriatric patients (age 50-80 years).

**Go to:**

**Materials and Methods**

*Patients:* Patients attending the O.P.D and I.P.D of the Department of *Kayachikitsa* and cases referred by other departments of the Institute for Post Graduate Teaching and Research in Ayurveda hospital, Gujarat Ayurved University, Jamnagar, fulfilling the criteria of inclusion were selected for the present study. An elaborative case taking proforma, incorporating all the aspects of the disease in Ayurvedic and Modern parlance was specially designed for the purpose.

*Drugs:* *Makandi* (*Coleus forskohlii* (Willd.) Briq.) root (tuber) - *Ghana vati* and tablets of its powder were prepared in the pharmacy of Gujarat Ayurved University, Jamnagar.

*Diagnostic criteria:* The standard diagnostic criteria of the World Health Organization (WHO)/International Society of Hypertension (ISH) (2004)[11] and Joint National Committee (JNC) VI[12] for Prevention, Detection, Evaluation, and treatment of High Blood Pressure was adopted in selecting patients for the study.

*Inclusion criteria:* Patients above 50 years and below 80 years of age, presenting with the classical symptoms of hypertension were selected for the study. Patients having systolic blood pressure >140 mm of Hg and ≤ 180 mm of Hg and diastolic blood pressure >90 mm of Hg and ≤ 110 mm of Hg were selected for the study.

*Exclusion criteria:* Patients below 50 years and above 80 years of age with systolic blood pressure <140 mm of Hg and >180 mm of Hg and diastolic blood pressure <90 mm of Hg and >110 mm of Hg were excluded from the study. Patients having major illness like severe diabetes Mellitus (DM), tuberculosis, major endocrine disorders, malignancies, Human immunodeficiency virus (HIV) or renal accelerated and malignant hypertension and other serious systemic illness were excluded from the study.
Investigation: Hematological investigations like Hemoglobin %, Total Leucocyte Count, Differential Leucocyte Count, Erythrocyte Sedimentation Rate, Packed Cell Volume, Total Red Blood Cell count and platelet count were done, as also urine and stool for routine and microscopic examination. Biochemical investigations like FBS, complete lipid profile, blood urea, serum creatinine, uric acid, and serum calcium were done, to rule out any other pathology. Serum Apolipoprotein B-100 was investigated as a biomarker for the elderly hypertensive patients.

Study design: It was a randomized clinical study. The study design was approved by the Institutional Ethics Committee. Informed consent was taken from the patients before including them in the trial.

Management of the patients

Drug dosage, duration, and method of administration:

- **Grouping:** The selected patients were randomly divided into two groups:
  - **Group-I** — Patients of this group were given *Makandi Ghana vati*-500 mg two t.d.s. after breakfast, lunch, and dinner, for two months, with lukewarm water as *anupana*. In this group, out of a total of 27 registered patients, 21 completed the treatment, and the remaining six stopped against medical advice.
  - **Group-II** — Patients of this group were given *Makandi Churna* tablet-700 mg two t.d.s. after breakfast, lunch, and dinner for two months, with lukewarm water as *anupana*. In this group, a total of 22 patients were selected, out of which 20 completed the treatment and two stopped it against medical advice.

Psychological counseling was done for all patients in both the groups.

Pathya - Apathya: The patients were advised to follow correct dietary habits and avoid unhygienic, stale food, reduce intake of extra salt, avoid *papada, chutneys, pickles*, and so on. Mild-to-moderate exercise as per their capacity was suggested. They were consulted for modification in diet and lifestyle, to rule out the causative factors of hypertension.

Follow-up: A follow-up study was carried out for one month.

Criteria for assessment

Changes in the subjective parameters of the specific rating scales were recorded at two-week intervals. Changes in systolic and diastolic blood pressures in both sitting and supine positions were assessed weekly. A specific rating scale for geriatric signs and symptoms,[13] *Manasa Pariksha Bhava* (Mental factor examination),[14] *Manasa Vibhrama pariksha*, for symptomatology,[15] and Brief Psychiatric Rating Scale[16] were utilized to assess the effect of the therapy. The total effect of the therapy in each patient was evaluated after completion of the treatment.

Criteria for the overall assessment of therapy
The total effect of the therapy was assessed considering the overall improvement in the signs and symptoms, reduction in blood pressure, and improvement on the ‘Brief Psychiatric Rating Scale’. After completion of the treatment course and in the follow-up period, the total effect was derived from the following formula:

$$\frac{\text{Total BT - Total AT}}{\text{Total BT}} \times 100$$

where BT is the mean score before treatment and AT is mean score after treatment

The obtained results were measured according to the grades given below,

<table>
<thead>
<tr>
<th>Grade</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Complete remission</td>
<td>100%</td>

<tr>
<td>Unchanged</td>
<td>&lt;25% Improvement</td>
</tr>
</tbody>
</table>

**Statistical analysis**

The information gathered on the basis of the observations was subjected to statistical analysis. The Paired ‘t’ test[17] was used to check the significance of the subjective and objective criteria and to compare the effect of the therapy on the two groups. The ‘\(\chi^2\)'-test[18] was carried for subjective criteria and the Unpaired ‘t’ test[19] for the objective criteria. The obtained results were interpreted at \(P < 0.05\), \(P < 0.01\), and \(P < 0.001\) significant levels.

Go to:

**Results and Discussion**

**Effect of the therapies on systolic and diastolic blood pressure and pulse pressure**

The effect of the therapy on systolic blood pressure (sitting position) shows 12.07 and 10.75% relief in groups I and II, respectively. The effect of the therapy on diastolic blood pressure (sitting position) shows 9.80 and 8.65% relief in groups I and II, respectively. The effect of the therapy on systolic blood pressure (supine position) shows 12.99 and 13.25% relief in groups I and II, respectively. The effect of the therapy on diastolic blood pressure (supine position) shows 10.10 and 10.75% relief in groups I and II, respectively. The effect of the therapy on pulse pressure (sitting position) shows 15.79 and 14.10% relief in groups I and II, respectively.
The effect of the therapy on pulse pre
ssure (supine position) shows 17.61 and 17.23% relief in
groups I and II, respectively. Statistically in all these parameters, both groups ha
ve shown highly significant results ($P < 0.001$). On applying the unpaired ‘t’ test for comparison, no
significant results have been obtained.

Thus, on observing the effects on blood pressure and pulse pressure, a mild fall in systolic as
well as diastolic blood pressure in both sitting and supine positions was found in both the groups,
which was statistically highly significant. This finding showed the efficacy of the treatment in
reducing blood pressure and proved that *Makandi* was an effective anti-hypertensive. Although
the reduction was small over a treatment of two months in the geriatric population, it could be
taken in order to regulate blood pressure over a long period. Comparatively, the overall reduction
in blood pressure was good in the treatment of group I, that is, *Makandi Ghan Vati*. As *Ghana*
is the concentrated form of the drug, with the highest potency, it obviously got better results.

**Effect on chief complaints**

The treatment in group I showed better improvement in *Bhrama* (67%), *Tamodarshana* (62%),
*Klama* (52%), *Alpanidra* (54%), *Shwasa* (55%), *Gurugatrata* (67%), and *Alasya* (67%). Group II
showed good improvement with *Shirashula* (52%), *Bhrama* (50%) *Tamodarshana* (60%), *Klama*
(60%), *Alpanidra* (50%), *Santap* (53%), *Shwasa* (59%), *Shrama* (57%), *Pipasa* (50%),
*Gurugatrata* (50%), and *Alasya* (75%). When the paired ‘t’ test was applied, to analyze the
results statistically, all the above-mentioned results were found to be highly significant, except
the one in *Alpanidra* in group II, which was non-significant. On applying the Chi square test,
Group I was found to be better in *Bhrama*, *Gurugatrata*, and *Krodhaprachurata* than Group II.

On analyzing the above results it is clear that the treatment in both groups I and II is good. It can
be stated that *Makandi*, either in the *Ghana vati* form or in the *churna* tablet form is an effective
treatment remedy for the treatment of hypertension.

**Effect on geriatric signs and symptoms and body mass index**

No significant or remarkable change was observed in any sign of aging in the studied geriatric
population. The finding supported the fact that after the age of 50 years, the natural aging
changes that occurred in various systems of the body could not be reversed. What Ayurvedic or
any treatment modality could achieve was to prevent further degenerative changes and improve
the quality of life. These objectives were fulfilled by the present treatment modality.

Group I had shown 2.60% while Group II had shown 2.38% of reduction in body mass index
(BMI). Statistically both the results were found highly significant ($P$ value $< 0.001$). Obesity has
been widely claimed for its role in the manifestation of HT. The increase in body weight in the
population is a critical factor in the increase in the prevalence of hypertension. Weight loss in
overweight or obese persons can prevent or delay the onset of hypertension. The *Meda dushti*
in case of obesity may be the cause for the obstruction of *Vyana vata*, leading to
hypertension. The obtained results can be due to the *Tikta, Katu rasa*, and *Ushna Virya* of the
trial drug. *Tikta rasa* causes *kleda, meda, vasa*, and *mutra upashoshana*, having properties of
*Deepana, Pachana, Shodhana*, and *Lekhana*, which are helpful for removing the obstruction.
from the Srotasa, and thus, responsible for Srotoshodhana. The Ushna Virya by removing the underlying obstruction helps to regain the normal functioning of Vata.

**Effect on Manasa Pariksha Bhava and Manasa Vibhrama Pariksha**

Among the Manasa Bhava, mild improvement in Moha (13.33%), Shoka (22.22%), Harsha (17.64%), and Bhaya (14.28%) was observed in the treatment with Group I. It also showed improvement in Buddhi Vibhrama (75%). Group II failed to show any remarkable effect on these parameters. The psychology is obviously disturbed in the geriatric population and they need more supportive psychotherapy through social and familial support, rather than medicine, to satisfy the inner instincts and to adapt to the physical and psychological changes occurring in the body and mind. Medicine can play a limited role in changing the psychological parameters.

**Effect on brief psychiatry rating scale**

In brief, the psychiatry rating scale of Group II showed better improvement in somatic concern, anxiety, guilt feeling, and depressed mood (50% each). Group I showed better improvement in tension (50%). All other symptoms were seen mildly improved in both the groups. It was clearly seen that Group II showed better results in the symptoms on the brief psychiatry rating scale.

**Effects on the hematological and biochemical parameters**

When the effects on the hematological and biochemical parameters were observed, no remarkable changes were observed in any of the parameters in both the groups. Group I had shown 11.81% increase in serum HDL, which was found statistically highly significant \( P < 0.01 \). Group II showed 8% increase in serum HDL. The treatment in Group I had also shown a 13.69% decrease in blood urea and a 7% decrease in serum creatinine, with statistically significant \( P < 0.05 \) and highly significant \( P < 0.01 \) results, respectively. In both these parameters Group II had shown 10 and 1% increase, respectively. In the serum cholesterol, Group II had shown a 4% decrease, while Group I showed a 3% increase. Statistically Group II showed highly significant \( P < 0.01 \) and Group I showed an insignificant result. In case of the investigation of a biomarker, serum Apolipoprotein-B 100, neither percentage wise nor a significant remarkable change was observed in any of the groups. In all other investigations, both the groups showed statistically non-significant results.

On comparison by unpaired ‘t’ test, Group I showed significantly better results in decreasing serum creatinine and increasing serum HDL level than Group II, whereas, Group II was found to be significantly better in reducing the serum cholesterol than Group I.

All the changes were within normal physiological limits. The findings on these hematological and biochemical profiles proved the safety and efficacy of the drugs under trial.

**Overall effect of therapy**
On analyzing the overall effect, it was observed that Group I, that is, treatment with Makandi Ghan Vati, showed comparatively better results than Group II [Figure 1]. The probable mode of action and the reason behind this is as discussed below.

![Figure 1](image)

Overall effect of therapy

**Probable mode of action of Coleus Forskohlii (Willd.) Briq. (Makandi)**

According to Vagbhata, the drug acts by its Rasa, Vipaka, Virya, Guna, and Prabhava.[21] Normally the effect of Rasa is less than that of Vipaka. The effect of Vipaka is less than that of Virya, which further is less than the effect of Prabhava, provided all are present in equal proportions.[22]

**Rasapanchaka[23]**

- **Rasa**: Tikta, katu, Madhura
- **Guna**: Tikshna, Vikasi
- **Veerya**: Ushna
- **Vipaka**: Kanda-Madhura vipaka

The probable effects of Makandi produced by its various properties are summarized below:

**Tikta Rasa** *(bitter taste)*

*Tikta rasa*[24] itself is not delicious, but when added with other things it promotes deliciousness. It is having Deepana, Pachana, Shodhana, Lekhana, and Shleshmopashoshana properties, which show that it promotes proper digestion, purification of the body, and depletion of Kapha, which can cause obstruction in the pathways of Vyana Vata. It has the properties[25] of kleda, meda, vasa, and mutra upashoshana, which are also helpful in the treatment of hypertension. Kleda and Meda are the factors that are involved in the pathophysiology of hypertension. Among the six Rasas, *Tikta rasa* is mentioned as ‘Laghutama’,[26] the property that is against the ama guna which is *Guru* in nature. Thus, by counteracting ama, it again helps to alleviate the disturbed pathophysiology in hypertension. Also because of this basic structure of Mahabhuta with Akasha and Vayu, it is supposed to have highest penetrating capacity and reach the subtlest level of the channels and the mind. *Tikta* can cause Pralhada (delightfulness).[27] Thus, it is very helpful in the treatment, as it is the remover of obstruction, in the case of hypertension. The *Rasa* is *Pitta Shamaka*, the second dominant *dosha* in geriatric hypertension.

**Madhura Vipaka**

*Makandi Kanda* possesses *Madhura Vipaka*, which is the finally converted *Rasa* after metabolism by Agni.[28] *Madhura Vipaka* alleviates the *Vata dosha*, stimulates the production of
normal *Kapha*, promotes semen, and helps in the proper elimination of stool and urine.\[29\] *Madhura* also can cause *Aalhada*, that is, soothing and delightfulness.\[30\] Sushruta states that *Madhura* can produce *Soumanasya* (sense of well-being), *Bala* (power), *Utsaha* (enthusiasm), *Harshana* (pleasure), and *Sukham* (happiness).\[31\] These are important qualities to alleviate the disturbed physio-psychopathology in hypertension.

**Ushna Virya**

*Ushna Virya* is again helpful in stimulating *Agni* and *Amapachana*, alleviating the vitiated *Vata* by removing the obstruction, and dominating its *sheeta* property. It helps in the dilatation of channels, thus providing a sufficient space to flow.

**Guna**

*Makandi* possesses important properties like *Tikshna* and *Vikasi*. By the virtue of the *Tikshna gunas* it can penetrate at a subtler level of channels, to remove the obstruction and by virtue of *Vikasi guna*, it can spread all over the body within a short time span, which is useful in the treatment of hypertension.

**Other actions and uses**

As per the classics, *Makandi* possesses *Deepana*, *Ruchi Vardhaka*, *Pathya*, *Jathara Roga Nashaka*, *Agni Dipaka*, *Ruchya*, and *Balakaraka* properties, which are also synergistic in the treatment of hypertension. It can destroy the diseases of the *Pleeha*, *Vata*, and *Kapha Vikaras*. It also cures *Gulma*, *Udara*, *Anaaha*, and *Sheeta Jwara*. Its *Kanda* (root tuber) is useful in *Pandu*; it is *Shopha Nashaka*, *Krimi*, *Pleeha*, *Pandu*, *Gulma*, *Samgrahani*, *Udara*, and *Arsha Roga Nashaka*.

**Difference between the pharmacological action of Ghana vati Kalpana and Churna Kalpana**

Properties of the drug also depend on the form of the administered drug, because the particular changes are created at all the physical, chemical, and metaphysical levels according to that particular procedure of the preparation (type of *Kalpana*). The same drug can have different properties (*Gunantarani*) according to the different types of the preparations (*Kalpanavisheshena*).\[32\] The study has proved this quotation.

The main procedural difference between the two forms is *Agni Samskar*. When preparing the *Ghana vati*, first the decoction of the drug is prepared and the filtered decoction is again heated, so that it concentrates to a solid form. In this method, the active ingredients of the drug have been under abundant heat for a prolonged time, which may increase or decrease the potency of the drug. Generally it is advised to prepare the *Ghana vati* of those drugs only, the active ingredients of which remain stable on heating and still the potency increases so as to increase the therapeutic efficacy of the drug. The advantage of *Ghana vati* is a more therapeutic efficacy with a lower dose, with a high level of palatability.
In the second group, tablets prepared from the powder of the drug were administered to the patients. In this form, the drug does not undergo any direct heating mode. It is the form made, so the drug is easy to take and is palatable. In this trial, therefore, it was decided to work critically on both forms of the drug Makandi.

After preparing the Makandi Ghan vati and Makandi powder, the estimation of the active ingredient ‘forskolin’ was done by using the HPLC quantitative analysis method.[33] It was observed that forskolin was present, 2.40 mg/500 mg in Ghana vati, and 2.31 mg/700 mg in the churna tablet. Thus, it was evident that the active ingredient was more in the Ghana vati form than in the churna tablet form.

**Pharmacological actions of Coleus forskohlii (Willd.) Briq. (Makandi)**

Forskolin is the extract from the tubers of the Coleus forskohlii (Willd.) Briq. plant, which has been proven to have blood pressure lowering and antispasmodic effects. It was first described as an activator of adenylate cyclase in rabbit heart membranes, in 1981 (Metzer and Linder, 1981).[34] The unique ability of forskolin to activate the enzyme Adenylate cyclase in the absence of a functional guanine nucleotide regulatory protein, strongly suggested that forskolin was a unique agent, capable of activating the catalytic protein directly (Seamon and Daly, 1981).[35] Also, in the textbook of modern science[36] it is mentioned that adenylate cyclase can be stimulated directly by the administration of forskolin, which bypasses both the beta receptor and G protein.

The hypotensive effects of forskolin are observed in deafferented as well as in the spinal transected cat, and suggested that lowering of blood pressure is not mediated by the central effects of forskolin, but is rather due to the direct peripheral vasodilatory actions, through its smooth muscle relaxation property.[37] Activation of adenylate cyclase further increases the amount of cyclic adenosine monophosphate (cAMP) in the cells. cAMP is the most important cyto-regulatory compound. This activation of Adenylate cyclase in the smooth muscles of the blood vessels by forskolin, resulting in an increase of cyclic AMP levels, may be a mediating factor for the relaxation of smooth muscles, which further results in vasodilatation, hence leading to a decrease in blood pressure.

It also had a spectrum of other actions like positive ionotropic, anti-glaucoma, anti-inflammatory, anti-platelet aggregation, anti-metastatic, bronchospasmolytic;[37] body weight reduction by increasing lean body mass,[38] and so on, all of which attributed to its ability to increase the amount of cAMP in the cells.

Lukewarm water was taken as an anupana. Its various properties like Dipana, Pachana, Vatanulomana, and so on, are mentioned in the classics. Some role of these actions, in the outcome of the therapy, can also be considered. It can be suggested to carry out further extensive studies on various permutations and combinations of different forms and doses of the drug. This study can be referred for the baseline idea.

**Go to:**
Conclusion

The study has revealed the efficacy of the treatment in reducing BP, and has proved that Makandi is an effective anti-hypertensive. On analyzing the overall effect, Group I has shown better results than Group II. The reason behind this may be that in the Ghana preparation the drug is in a more concentrated form, with the highest potency in a lower dose than in the Churna tablet form. Group I has also shown encouraging results on renal function by lowering the blood urea and serum creatinine level with improvement in HDL — good cholesterol, while Group II has shown better improvement in serum cholesterol. The results have also shown that the same drug can have different properties according to the type of the preparation. It can be stated that Makandi either in the Ghana vati form or in the Churna tablet form is an effective treatment remedy for the treatment of hypertension. The study has provided enough scope to future research workers interested in Makandi vis-a-vis hypertension, to have a large sample study for a longer duration. If patients are administered Makandi on the early detection of hypertension then the unnecessary use of powerful synthetic drugs, causing a number of adverse effects, can be effectively avoided.
